#### Final Exam, 2020-04-23

#### Question 1.

By U we denote the set of all positive integers between 1 and 120. This is the *universe* in which we define several subsets:

$$\left\{ \begin{array}{l} A = \{x \in U \mid 2 \mid x\}, \\ B = \{x \in U \mid 3 \mid x\}, \\ C = \{x \in U \mid 5 \mid x\}, \\ X = \{x \in U \mid 2 \mid x \vee 3 \mid x\}, \\ Y = \{x \in U \mid (3 \mid x \wedge 5 \mid x) \vee \neg (2 \mid x)\}. \end{array} \right.$$

- (A) Express X using the sets A, B, C (using set union  $V \cup W$ , set intersection  $V \cap W$ , set complement  $\overline{V}$  operations).
- **(B)** Express *Y* using the sets *A*, *B*, *C* in a similar way.
- (C) Find |X| the size of the set X.
- **(D)** Find |Y| the size of the set Y.

## Question 2.

Let A and B be sets with sizes |A| = 8 and |B| = 5 and  $|A \cap B| = 3$ .

Calculate the largest and the smallest possible values for each of the following set sizes:

- (A)  $|A \cup B|$ .
- **(B)**  $|A \times (B \times B)|$ .
- (**C**)  $|\mathcal{P}(\mathcal{P}(A \cap B))|$  the powerset of a powerset of  $A \cap B$ .
- **(D)**  $|A \oplus B|$  the symmetric difference of the sets A and B.

## Question 3.

Consider the following recurrent sequence:

$$\begin{cases} a_0 = 3 \\ a_1 = 4 \\ a_{n+2} = 5a_{n+1} - 6a_n, \text{ if } n \ge 0 \end{cases}$$

Assume that  $b_n$  is another sequence satisfying the recurrence rule

$$b_{n+2} = 5b_{n+1} - 6b_n$$
, if  $n \ge 0$ 

(The first two members  $b_0$ ,  $b_1$  are not known.)

- (A) Write the first 6 members of this sequence  $(a_0, \ldots, a_5)$ .
- **(B)** Write the characteristic equation for this sequence.
- (C) Write the general expression for an arbirary sequence  $b_n$  satisfying the recurrent expression as a sum of two geometric progressions (you can leave unknown coefficients in your answer; just explain which ones they are).
- **(D)** Write the formula to compute  $a_n$  (that would satisfy the initial conditions  $a_0 = 3$  and  $a_1 = 4$ ).

#### **Question 4.**

Consider this code snippet in Python:

```
n = 1000
sum = 0
for i in range(1, n*n+1):
    for j in range(1,i+1):
        sum += i % j
```

And a similar one in R:

```
n <- 1000
sum <- 0
for (i in 1:(n*n)) {
    for (j in 1:i) {
        sum <- sum + i %% j
    }
}</pre>
```

- (A) Explain in human language what this algorithm does.
- **(B)** Denote by f(n) the number of times the variable 'sum' is incremented. Write the Big-O-Notation for f(n). Find a function g(n) such that f(n) is in O(g(n)). (If there are multiple functions, pick the one with the slowest growth.)
- (C) Express the function f(n) precisely how many times 'sum' is incremented in terms of variable n.

### Question 5.

Let *A* be the set of all positive divisors of the number 120 (including 1 and 120 itself).

- (A) What is the multiplication of all numbers in the set *A*?
- **(B)** Express this number as the product of prime powers.

## Question 6.

Define the following binary relationship on the set of integer numbers  $\mathbb{Z}$ : We say that aRb (numbers  $a,b\in\mathbb{Z}$  are in the relation R) iff

$$\begin{cases} a - b \equiv 0 \pmod{11} \\ a - b \equiv 0 \pmod{12} \\ a - b \equiv 0 \pmod{13} \end{cases}$$

Item	Statement	True or False?
(A)	R is reflexive	
<b>(B)</b>	R is symmetric	
(C)	R is antisymmetric	
( <b>D</b> )	R is transitive	
(E)	$aRb  ext{ iff } a = b$	

For all items where you answered 'FALSE', specify a counterexample (values for some numbers that would make the condition true, but the conclusion false). If the statement was true, write "none".

- (A) counterexample: ...
- **(B)** counterexample: ...
- (C) counterexample: ...
- (**D**) counterexample: ...
- (E) counterexample: ...

#### **Question 7.**

Four people *A*, *B*, *C*, *D* each has his own hat. After the meeting they leave their building in a hurry, everyone grabs some hat at random so that all 4! permutations of the hats have equal probabilities.

Let the random variable X denote the number of hats that were picked up correctly. (For example, if the hat assignment is this:  $(A \rightarrow A, B \rightarrow B, C \rightarrow D, D \rightarrow C)$ , then X = 2, because two people got their own hats.)

(A) Find E(X) - the expected value of X.

**(B)** Find V(X) - the variance of X.

### Question 8.

There was a crooked man who had a crooked 1 euro coin. On lucky days it would flip the \*heads\* with probability  $p=\frac{2}{3}$ , and the \*tails\* with probability  $p=\frac{1}{3}$ , but on unlucky days it was the opposite  $(p(\text{heads})=\frac{1}{3}, \text{ but } p(\text{tails})=\frac{2}{3})$ . There were equal probabilities of  $\frac{1}{2}$  for lucky and unlucky days.

One morning he flipped the coin 5 times and altogether got three *heads* and two *tails*.

Let us introduce the following events:

- *E* (evidence): Five coin tosses result in three *heads* and two *tails*.
- *H* (hypothesis): The current day is lucky.
- (A) Find P(E|H) the conditional probability of E given that the day is lucky.
- **(B)** Find  $P(E|H) \cdot P(H)$  the probability that the day is lucky and *E* happens.
- (C) Find  $P(E|\overline{H})$  the conditional probability of E given that the day is not lucky.
- **(D)** Find  $P(E|\overline{H}) \cdot P(\overline{H})$  the probability that the day is unlucky and E happens.
- (E) Find P(E) as the sum of two probabilities (E happened on a lucky day and also E happened on unlucky day).
- (**F**) Find the conditional probability P(H|E) the likelyhood that the croocked man has a lucky day, given that the event E has happened.

## Question 9.

Figure 1. A tree for an expression.

The syntax tree describes an algebraic expression (please note the difference between the unary minus

that flips the value of the variable y and the binary minus that subtracts the two subexpressions: -y and  $6 \times 3$ ).

- (A) Write the preorder DFS traversal of this tree.
- (B) Write the inorder DFS traversal of this tree.
- (C) Write the postorder DFS traversal of this tree. *Note*. In all 3 answers denote the unary minus with the tilde sign ~, but the regular/binary minus with –.

## Question 10.

Figure 2. A graph with 9 vertices.

Run the Prim's algorithm on the weighted graph in Figure 2, start growing the tree from the vertex *I*.

Newly Added Edge

What is the total weight of the obtained Minimum Spanning Tree?

#### **Answers**

Every problem is worth 15 points. The total for this final is 150 points.

## Question 1.

- (A)  $X = A \cup B$  (Boolean OR means set union)
- **(B)**  $Y = (B \cap C) \cup \overline{A}$  (Boolean and means set intersection; negation means set complement)
- (C)  $|X| = |A| + |B| |A \cap B| = 60 + 40 20 = 80$  (principle of inclusion-exclusion).
- **(D)** |Y| is all odd numbers and also four even numbers divisible by 15 (30, 60, 90, 120). The total is 60 + 4 = 64. *Grading.* 
  - Each correct answer is 3 points (total 12).
  - Explaining both (C) and (D) is another 3 points (total 3).
  - Using wrong set notation (∧ instead of ∩ etc.) divides the number of points in half.
  - 68 instead of 64 is 2 points (instead of 3).

#### **Ouestion 2.**

In all the answers the largest and the smallest value are equal, because we know exactly how the two sets intersect; how many elements belong to just one of the sets *A*, *B*, and how many elements belong to the both sets.

- (A)  $|A \cup B| = |A| + |B| |A \cap B| = 8 + 5 3 = 10$  (the principle of inclusion-exclusion).
- **(B)**  $|A \times (B \times B)| = 8 \cdot 5 \cdot 5 = 200$
- (Cartesian product has size that is the product of all participant sets: one can combine three elements from the sets *A*, *B* and *B* in this many ways).
- (C)  $2^{2^3} = 2^8 = 256$  (the number of elements in the powerset of any set *X* can be obtained by raising 2 to the power |X|).
- **(D)**  $|A \oplus B| = (8-3) + (5-3) = 7$  (we remove the common elements from both *A* and *B*). *Grading.* 
  - Each correct answer is 3 points (total 12).
  - Expressions or verbal explanations of the answers is 3 points (total 3).

# Question 3.

**(A)** 
$$a_0 = 3$$
,

$$a_1 = 4$$
,

$$a_2 = 5 \cdot 4 - 6 \cdot 3 = 2$$
,

$$a_3 = 5 \cdot 2 - 6 \cdot 4 = -14$$
,

$$a_4 = 5 \cdot (-14) - 6 \cdot 2 = -82,$$

$$a_5 = 5 \cdot (-82) - 6 \cdot (-14) = -326,$$

$$a_6 = 5 \cdot (-326) - 6 \cdot (-82) = -1138.$$

**(B)** The characteristic equation is obtained, if we try to find  $a_n$  in the form of a geometric progression  $r^n$ :  $r^{n+2} = 5r^{n+1} - 6r^n$ , or  $r^2 - 5r + 6 = 0$ . It has two roots:  $r_1 = 2$ ,  $r_2 = 3$ .

(C) The general form of the expression for any iterative sequence  $b_n$  satisfying the relationship  $b_{n+2} = 5b_{n+1} - 6b_n$  is as follows:

$$b_n = A \cdot 2^n + B \cdot 3^n,$$

where A, B are two constants that depend on the two initial values of the sequence  $b_n$ .

**(D)** We need to solve a system of two equations, to ensure that the formula  $a_n = A \cdot 2^n + B \cdot 3^n$  has correct values for n = 0 and n = 1. We get the following system:

$$\begin{cases} A+B=3, \\ 2A+3B=4. \end{cases}$$

Substitute B = 3 - A into the second equation. We get that 2A + 9 - 3A = 4 and A = 5. We also get that B = -2. Therefore the exact formula to calculate the sequence  $a_n$  is this:

$$a_n = 5 \cdot 2^n - 2 \cdot 3^n$$
, where  $n \ge 0$ .

This actually works, if we plug in the values calculated in (A) for n = 0, ..., 6.

- Answer in (A) is 4 points.
- Answer in (B) is 4 points.
- Answer in (C) is 3 points.
- Answer in (D) is 4 points.

# **Ouestion 4.**

- (A) The algorithm takes all numbers i from 1 to  $n^2$  and divides them by all the smaller numbers j < i, and adds up all the obtained remainders.
- (C) The outer loop is repeated  $n^2$  times. The inner loop is repeated  $1+2+3+...+n^2$  times. This is an arithmetic progression. The sum of an arithmetic progression is the arithmetic mean of the first and the last member multiplied by the number of members:

$$f(n) = \frac{1+n^2}{2} \cdot n^2 = \frac{n^4+n^2}{2}.$$

**(B)** f(n) is in  $O(n^4)$ . Therefore we can take  $g(n) = n^4$ . We can pick another g(n) that is multiplied by some nonzero constant (such as  $\frac{n^4}{2}$  or  $17n^4$  or anything else - that also counts as a valid answer). Certainly, f(n) is also in  $O(n^k)$  for any k > 4, but the function  $g(n) = n^4$  is the slowest growing.

- Answer for (A) is 5 points.
- Answer for (B) (any 4th degree polynomial of n) is 5 points. An attempt to estimate some arithmetic progression with a different upper limit (say, 1 + 2 + ... + n) gets 2 points.
- Answer for (C) is 5 points. If the answer is provided just for n = 1000 (not for any variable), then it is 4 points.

#### **Question 5.**

(A) If expressed as a product of two positive integers 120 = ab, one of the divisors a or b would be smaller than  $\sqrt{120} \approx 11$ , and the other one would be bigger. We can easily list all the ways to express 120 as a product of two integers:

$$1 \cdot 120 = 2 \cdot 60 = 3 \cdot 40 = 4 \cdot 30 =$$
  
=  $5 \cdot 24 = 6 \cdot 20 = 8 \cdot 15 = 10 \cdot 12$ .

and there are no other factorizations, since all the divisors less than 11 are already listed. Multiplying them all together would give

$$(120)^8 = 42998169600000000$$

**(B)** As a product of prime factors:

$$(120)^8 = (2^3 \cdot 3 \cdot 5)^8 = 2^{24} \cdot 3^8 \cdot 5^8.$$

Grading.

- Correct item (A) is 7 points (also floating point answers were fine not all had easy access to the big integer arithmetic).
- Correct item (B) is 8 points.

## Question 6.

Item	Statement	True or False?
(A)	R is reflexive	TRUE
(B)	R is symmetric	TRUE
(C)	R is antisymmetric	FALSE
( <b>D</b> )	R is transitive	TRUE
(E)	$aRb  ext{ iff } a = b$	FALSE

- (A) Counterexample: None
- (B) Counterexample: None
- (C) Consider counterexample a = 0,  $b = 11 \cdot 12 \cdot 13 = 1716$ . While it is true that aRb and bRa, nevertheless  $a \neq b$ .
- **(D)** Counterexample: None
- (E) Counterexample is same as in (C): a = 0, b = 1716.

Grading.

- One correct answer is 2 points (total 10).
- Counterexamples for (C) and (E) is 5 points (they are, in fact, the same).

#### Question 7. Answer: 17

- For 1 of 24 permutations X = 4 (all hats stay in place),
- For 0 permutations X = 3 (it is not possible for exactly three hats to stay in place, because then the 4th hat also returns to its owner),
- For 6 of 24 permutations X = 2 (there are  $\binom{4}{2} = 6$  ways how to pick 2 hats that stay in place; and the remaining two hats can switch places only in one way),

- For 8 of 24 permutations X = 1 (there are  $\binom{4}{1} = 4$  ways how to pick 1 hat that stays in place; and the remaining three hats can rotate in two ways).
- For the remaining 24 (1 + 6 + 8) = 9 permutations X = 0 (no hats stay in place).

Table 1
Random Variable X for the Hat Problem

Permutation         X         X - E(X)         (X - E(X)) <sup>2</sup> ABCD         4         3         9           ABDC         2         1         1           ACBD         1         0         0           ADBC         1         0         0           ADCD         2         1         1           BACD         2         1         1           BADC         0         -1         1           BCAD         1         0         0           BCDA         0         -1         1           BDCA         0         -1         1           BDCA         1         0         0           CABD         1         0         0           CDAB         0         -1         1           CDBA         1		7

<b>Mean</b> 1 0 1	DCBA	0	-1	
	Mean	1	0	1

- (A)  $E(X) = \frac{1}{24} \cdot 4 + \frac{6}{24} \cdot 2 + \frac{8}{24} \cdot 1 = 1$ . This means that the expected number of hats that stay in place is exactly 1.
- **(B)** For all 24 permutations, subtract the value E(X) = 1 from every hat experiment outcome. Define  $x_1, \ldots, x_{24}$  all 24 values of the random variable X (exactly one value is 4, exactly six values are 2, exactly 8 values are 1, exactly 9 values are 0):

$$V(X) = \frac{\sum_{i=1}^{24} (x_i - 1)^2}{24} = \frac{24}{24} = 1.$$

Therefore, V(X) = 1 (variance also equals 1, but the unit of measurement is not hats but "hats squared"). Note. E(X) = 1 is the arithmetic mean over the column X, but V(X) = 1 is the arithmetic mean over the column  $(X - E(X))^2$  (see Table 1).

Grading (theoretically max=20, but most results are not that high).

• Correctly found E(X) is 5 point.

- Correctly found V(X) is 5 point.
- Justified computation for E(X) is 5 points.
- Justified computation for V(X) is 5 points.

## Question 8.

(A) P(E|H) is the outcome of the Binomial distribution: There are n = 5 coin-toss experiments; the probability of success for any single experiment is  $p = \frac{2}{3}$ (since we know that the day is lucky and hypothesis H holds). Therefore,

$$P(E|H) = {5 \choose 3} p^3 (1-p)^2 = 10 \left(\frac{2}{3}\right)^3 \left(\frac{1}{3}\right)^2 = \frac{80}{243}$$

**(B)**  $P(E|H) \cdot P(H) = \frac{80}{243} \cdot \frac{1}{2} = \frac{40}{243}$ , since  $P(H) = \frac{1}{2}$  (the *a priori* probability of a lucky day is exactly 1/2).

(C) P(E|H) is the outcome of the Binomial distribution: Again, there are n = 5 coin-toss experiments, but now the probability of a single experiment is just  $p = \frac{1}{3}$ . Therefore,

$$P(E|\overline{H}) = {5 \choose 3} p^3 (1-p)^2 = 10 \left(\frac{1}{3}\right)^3 \left(\frac{2}{3}\right)^2 = \frac{40}{243}$$

**(D)**  $P(E|\overline{H}) \cdot P(\overline{H}) = \frac{40}{243} \cdot \frac{1}{2} = \frac{20}{243}$ . **(E)** We can compute P(E) as the sum of two mutually incompatible events: event E can happen either on a lucky day or on an unlucky day:

$$P(E) = P(E|H) \cdot P(H) + P(E|\overline{H}) \cdot P(\overline{H}) = \frac{40}{243} + \frac{20}{243} = \frac{60}{243}.$$

**(F)** Use Bayes formula:

$$\begin{split} P(H|E) = & \frac{P(E|H) \cdot P(H)}{P(E|H) \cdot P(H) + P(E|\overline{H}) \cdot P(\overline{H})} = \\ = & \frac{P(E|H) \cdot P(H)}{P(E)} = \frac{\frac{40}{243}}{\frac{60}{242}} = \frac{2}{3}. \end{split}$$

Bayes formula is intuitive: It shows the proportion of the subcase  $P(E|H) \cdot P(H)$  (i.e. event E happens on a lucky day) out of the whole probability P(E) =  $P(E|H) \cdot P(H) + P(E|\overline{H}) \cdot P(\overline{H})$  (i.e. event E happens either on a lucky or unlucky day).

Grading (theoretically max=20, but most results are not that high).

- Any item from (A) to (E) is 3 points.
- Bayes formula or a similar expression finding the reverse conditional probability in (F) in 5 points.

#### Question 9.

- $(A) + : \sim y \times 6 \ 3 \ z \ 2,$
- **(B)**  $y \sim -6 \times 3 : z + 2$ ,
- (C)  $y \sim 6.3 \times -z : 2 +$ .

Note. In inorder traversal (B) we first visit the first subtree (e.g., y), and only then the parent node (e.g., unary minus ~). See (Rosen2019, p.811). Grading.

- · Each correctly written expression is
- Item (B) with switched order of the unary minus and its child node y is 3 points instead of 5.
- · Minor typos in single characters get 4 or 5 points.
- · Any major differences from the correct result do not get points.

# Question 10.

We start from vertex I. At every step we grow the tree by a single edge (so that it stays connected and the newly added edge has the smallest possible weight).

Step	Newly Added Edge
Step 1	IG, w = 1
Step 2	IE, w = 2
Step 3	ED, w = 1
Step 4	DC, w = 2
Step 5	CH, w = 2
Step 6	GA, w = 3
Step 7	AB, w = 2
Step 8	IF, w = 5

The total weight of all added edges (same as the total weight of the MST) is 18.

Figure 3. MST edges shown in blue.

### Grading.

- Incorrectly adding up weights could subtract 1 or 2 points from the total
- Adding 9 edge weights (or any other number instead of 8 weights) and getting incorrect sum is 11 points (instead of 15).
- Not showing the edges in answers (or displaying them in an order that differs from Prim's algorithm), but still getting something close to MST is about 8 points.
